

Extracting recipe ingredients from cookbooks

by
Torsten Knauf

A thesis presented for the degree of
Master of Science

Research Group for Communication Systems
at
Faculty of Engineering
Christian-Albrechts-Universität zu Kiel
Germany
31.03.2017

Supervisor: Prof. Dr.-Ing. Norbert Luttenberger
Dr.-Ing. Jesper Zedlitz

Abstract

Always do this one last, when knowing the things to praise yourself for :P

Acknowledgements

If I don't profit from nice people in these thesis, I have done something horrible wrong. So try to remember most of them here at the end... :)

1.2 Mein Beitrag

1.3 Structure of this thesis

The thesis is structured as follows:

Chapter 2

Motivation

I personally find it an interesting computer science challenge to extract ingredients from plain text and make them machine readable. But that would be a bad justification for a master thesis. Therefore this chapter points out some of many applications, which are possible, once the ingredients are extracted. Building a database manual for all these applications is way to time consuming, as pointed out in 3.4, what is a good justification and motivation for this master thesis.

(Ueda et al. 2011) build a **recipe recommendation system** for a cooking website, based on which ingredients are liked by the users and which not. WERT VON CHEFKOCH.DE

Beside that, there seems to exist a lot of effort about **diet, targeting the well being**. (Teng et al. 2012) analyse, how far a recipe is liked in relation with its nutrition information, which are based on the ingredient of the recipe. They also analyse how far an ingredient can be replaced through another ingredient, which is nice, if you want a low-fat alternative, or it is not available right now. (Freyne and Berkovsky 2010) as well as (Geleijnse et al. 2010) build a recipe recommendation, which prefer healthy recommendations. As before, the healthiness of a recipe is determined through its used ingredients.

Social science is also possible through analysing recipes. For example (Henning 2008) analyses typical characteristics of cookbook through German history. She noticed that recipes before the 18.th century often contained ingredients, which should mask the taste of rotted food, what is clearly a sign for poverty and food shortage. Fasting meals covered about a third of many cookbooks, which emphasises the influence of the church at that time. First mentions of non-native ingredients and meals are indications for intercultural exchange. Rare and expensive ingredients are signs for prosperity while possible substitution of them for poverty. Another example is in (Ahn et al. 2011). They compare American and Asian culinary practice based on about 56.000 recipes.

Chapter 3

Making a cookbook machine readable

This chapter covers shortly, how a printed cookbook can be transformed into a machine readable format, which can be arbitrarily processed further. To achieve this, the cookbook has to be digitalised first. Afterwards it has to be enriched with meta data from an ontology.

3.1 Digitalisation

In general there are two different ways, how to digitalise a book. The first one is to scan each side and let an optical character recognition program extract the text of the scanned pictures. The second one is to type it manually into a computer.

The German Text Archive provides a collection of German texts from the 16th to the 19th century including our targeted cookbook *Davidis, Henriette: Praktisches Kochbuch für die gewöhnliche und feinere Küche. 4. Aufl. Bielefeld, 1849* in (Deutsches Textarchiv 2016). They digitalised it through double keying, meaning that two people independent of each other manually typed the book into the computer. Differences in their versions were revised by a third person. They have already enriched the book with *TEI: Text Encoding Initiative*-standard¹. TEI is a standard for representing printed text in digital form. As many as possible characteristics of the printed medium are kept through meta data. Its main purpose is for analysing in humanities, social sciences and linguistics.

Because we are only interested in extracting certain data from the recipes and not in linguistic analysis or something else, we have transformed the digitalised version as depicted in fig. 3.1 on the next page. The essence of this version is, that it is free of for us not relevant information like the encoding of the German *f* and has a clear structure.

</cue:recipe>

```

(b) Example transformed

Figure 3.1: A recipe from our cookbook

3.2 CueML ontology

An ontology is needed for automatic extraction and further processing of information. In computer science an ontology is a vocabulary with defined meaning. A general description for the use of ontologies can be found in (Berners-Lee et al. 2000).

Schema.org/Recipe is an existing ontology for recipes (Schema.org 2016). For example <http://cooking.nytimes.com> and <http://allrecipes.com> use it. An example usage is shown in fig. 3.2 on the next page and its main purpose is to support search engines as described in (Food Blogger Pro 2014) and (Schema.org 2016) ².

But it is not precise enough for further automatic culinary analysis like extracting the ingredients. As you can see in fig. 3.2 each line from the list of ingredients is marked as an ingredient. This is too inaccurate, because the concrete ingredient is not marked and neither its quantity nor unit. Therefore a computer cannot understand it.

Mom's World Famous Banana Bread
 By John Smith, May 8, 2009

 This classic banana bread recipe comes from my mom -- the walnuts add a nice texture and flavor to the banana bread.
 Prep Time: 15 minutes
 Cook time: 1 hour
 Yield: 1 loaf
 Tags: Low fat
 Nutrition facts:
 240 calories, 9 grams fat
 Ingredients:
 - 3 or 4 ripe bananas, smashed
 - 1 egg
 - 3/4 cup of sugar
 ...
 Instructions:
 Preheat the oven to 350 degrees. Mix in the ingredients in a bowl. Add the flour last. Pour the mixture into a loaf pan and bake for one hour.

(b) The same recipe enriched with markup

Figure 3.2: Schema.org/Recipe example from (Schema.org 2016)

That is why we came up with **culinary editions markup language (cueML)**. It is pronounced like Kümmel, which is the German word for caraway. CueML extends TEI, so that the structure of our cookbook can be obtained. Its vocabulary sticks close to Schema.org/Recipe, so that it profits from the already established schema and can easily be transformed into it, for the sake of search engines.

First of all we add the four attributes *quantity*, *unit*, *ref* and *target* to the *recipeIngredient* element. *Ref* is a reference to an ingredient element, which defines the ingredient, as elucidated later. When the ingredient is a composed ingredient like dumplings, the *target* attribute is used instead of *ref*. It should reference to a correlating recipe.

The ingredient element defines the ingredient. A *BLSref* attribute is a reference to the Bundeslebensmittelschlüssel³-key

```
Ingredients:
- <span itemp="recipeIngredient" quantity="3-4" ref="#F503000">3
  or 4 ripe bananas, smashed</span>
- <span itemp="recipeIngredient" quantity="1" ref="egg">1 egg</
  span>
- <span itemp="recipeIngredient" quantity="0.75" ref="cup" name="
  sugar">3/4 cup of sugar</span>
```

Listing 3.1: Example for cueML

Additionally we add an attribute *optional*, because we think it is not appropriate to simply state sugar is an ingredient in the case of "sugar if not sweet enough".

Last we also noticed, that ingredients can be alternatives to each other like in "hollandaise sauce or butter, mustard and a squeeze of lemon juice". Therefore we add an element *recipeIngredientAlternations* having arbitrary child elements *alt*, which enclose *recipeIngredient* elements.

An example is provided in appendix B. The complete cueML ontology is defined through a relaxing grammar, which can be found in appendix C. Due to the point, that Schema.org does not provide a grammar for Schema.org/Recipe, cueML includes also the rules for it. Personally I was surprised that they do not provide an official grammar, because that would provide a clear definition as well as an easy validation method. That is why we provide a grammar. But they state themselves, that "some data is better than none", meaning, that they want to tolerate wrong meta data for reducing the risk of getting no meta data at all. They state furthermore, that it makes it more easy to extend the language (Schema.org 2016)⁴. Obvious you cannot break, what is not defined.

3.3 Applying cueML to our recipes

Due to the point, that we wanted to extend Schema.org/Recipe, cueML should be applied to the list of ingredients as the former does. But our recipes have only a direction text, as you can see in fig. 3.1. CueML as well as Schema.org/Recipe is not well suited for direction text. The ingredient phrases are not always tied closely together. Besides they repeat themselves in the text and sometimes they appear in the form of "like the previous one but don't use onions". These points make it hard to apply cueML directly to the direction text. Therefore we decided to collect them

³<https://www.blsdb.de/>

⁴at <http://schema.org/docs/datamodel.html>

in an extra *meta*-element. Having extra sections for recipe yield, cook time and list of ingredients is way more nicer to read than only one direction text anyway. Appendix B shows a full example usage of cueML. A test with the testing tool for structured data from google⁵ reveals, that all extracting, which is already in place for Schema.org/Recipe, still works.

3.4 Need for automation

As mentioned in (Erdmann et al. 2000), manual tagging is time consuming and error prone. The approach to extract ingredients from recipes, which we will present in section 4.3, emphasises that. They state, that they need 50-100 fields per recipe. And in the evaluation of their approach they discovered mistakes done in manual tagging.

For tagging one recipe in our cookbook I need about 5 minutes. That means, that I would need more than 2 weeks, for tagging only the recipes from our cookbook. Building a big data pool this way is very time consuming and therefore expensive.

Hence automation, which has to be configured only once and can be applied to many resources afterwards, is clearly preferable.

⁵<https://search.google.com/structured-data/testing-tool>

Chapter 4

Related Work

In general there exists many works about extracting useful information from textual and unstructured resources. The superordinate term for this field of research is Text Mining. It was first mentioned in (Feldman and Dagan 1995) and an overview can be found in (Hotho et al. 2005).

The algorithms for extracting useful information depend highly on existing semi-structures, which can be taken advantage of. Here we present existing algorithms, which we found in the domain of cooking, and distinct their effort from this thesis. But before that we define precision and recall.

4.1 Precision & Recall

NOT HERE Precision and recall are metrics, which measure the quality of an information extracting algorithm.

$$Precision = \frac{\#(retrieved \cap relevant)}{\#retrieved}, \quad Recall = \frac{\#(retrieved \cap relevant)}{\#relevant} \quad (4.1)$$

They are defined as shown in eq. (4.1) according to (Hotho et al. 2005). A high precision states, that the algorithm does only find relevant information as intended. The ideal precision of one would mean, that all extracted data were useful. A high recall states, that the algorithm finds many of the total relevant information. The perfect score of one would mean, that all relevant information were found. Both are needed for the evaluation of an algorithm. If only considering precision, the algorithm could only find the information, which are obvious relevant and therefore find only view information, but having a high score this way. On the other side, if only considering recall, the algorithm could return everything. This way its score would have the perfect value of one. But both algorithm are obvious not good, which gets covered by a low value of the other formula.

4.2 Skip The Pizza

(*Skip The Pizza* 2012) is a project described on WordPress.org. The author wants to combine his two hobbies cooking and software engineering. For being able to answer questions like "How many ingredients does a typical recipe consist of?" or

"Which are the most frequent ingredients?", he extracts the ingredients of recipes from an open source platform at http://recipes.wikia.com/wiki/Recipes_Wiki.

The recipes have a consistent internal representation, which is shown in listing 4.1. The semi-structure, that after `== Ingredients ==` comes a list of ingredients, can be recognized easily. Per line is one ingredient enclosed within `[[ingredient name]]`. Using this semi-structure a regular expression is already good enough for extracting the ingredients from these recipes.

```
* Makes 6 to 8 servings

== Ingredients ==
* 2 tbsp extra virgin [[olive oil]]
* 3 cloves [[garlic]], finely chopped
[...]

== Directions ==
Heat olive oil and garlic in large skillet over low heat until
garlic begins to sizzle.
Add tomatoes, [...]

[[Category:Cathy's Recipes]]
[[Category:Garlic Recipes]]
[...]
```

Listing 4.1: Shortened example recipe from
http://recipes.wikia.com/wiki/Recipes_Wiki

4.3 Extracting Structured Data From Recipes Using Conditional Random Fields

The New York Times provides a cooking website with recipes¹. Their recipes are enriched with Schema.org/Recipes. For providing a recipe recommendation system based on ingredients, you have to extract the exact ingredients from a recipe, which is not enabled through this schema, as already discussed in section 3.2. Nevertheless they are able to extract them automatically. They use the provided structure from Schema.org/Recipe, that each ingredient phrase from the list of ingredients is marked as `recipeIngredient`, and Conditional Random Fields (CRF) for that. Their approach is described in (The New York Times 2015). Hence we introduce here CRF first and afterwards outline their implementation.

4.3.1 Conditional Random Fields

Given a vector of words, CRF wants to predict a suitable vector of labels. For example when the vector of words is *[1 tablespoon salt]*, we want to predict *[QUANTITY, UNIT, INGREDIENT]*, meaning 1 is a quantity, tablespoon a unit and salt an ingredient.

A detailed introduction to CRF can be found in (Sutton and McCallum 2012). Here we only want to give a quick overview about linear-chain CRF, because that is

¹<http://cooking.nytimes.com/>

the algorithm the New York Times uses. Therefore, when we write CRF, we mean linear-chain CRF.

Its starting point are vectors of words X , which have already correct vectors of labels Y . Such related sets of vectors are called training data. A joint probability distribution can be extracted from this training data, which states how likely a vector of words has a corresponding vector of labels. Taking the simplified assumption, that each label depends only on the previous label and that the current word depends only on the current label, leads to eq. (4.2). This can always be transformed into the form of eq. (4.3). The division with $Z(X, Y)$ ensures, that the value of $p(X, Y)$ is between zero and one. $1_{condition}$ is a function, which is one if the condition is true and zero otherwise. Smart indexing leads to eq. (4.4). Each f_k is called a feature function. The calculation of the Θ_k 's is a mathematical optimisation problem. Note that there is very likely no exact solution due to the simplified assumption of eq. (4.2).

$$p(X, Y) = \prod_{t=1}^T p(y_t|y_{t-1}) * p(x_t|y_t), \quad T = \#X \quad (4.2)$$

$$\begin{aligned} p(X, Y) &= \frac{1}{Z(X, Y)} \prod_{t=1}^T \exp\left(\sum_{i,j \in S} \Theta_{i,j} * 1_{y_t=i} * 1_{y_{t-1}=j} + \sum_{i \in S} \sum_{j \in O} \mu_{o,i} * 1_{y=i} * 1_{x_t=o}\right), \\ Z(X, Y) &= \sum_X \sum_Y \prod_{t=1}^T \exp\left(\sum_{i,j \in S} \Theta_{i,j} * 1_{y_t=i} * 1_{y_{t-1}=j} + \sum_{i \in S} \sum_{j \in O} \mu_{o,i} * 1_{y=i} * 1_{x_t=o}\right), \\ &\quad S = \text{all possible labels}, \quad O = \text{all possible words} \end{aligned} \quad (4.3)$$

$$\begin{aligned} p(X, Y) &= \frac{1}{Z(X, Y)} \prod_{t=1}^T \exp\left(\sum_{k=1}^K \Theta_k * f_k(y_t, y_{t-1}, x_t)\right), \\ Z(X, Y) &= \sum_{X,Y} \prod_{t=1}^T \exp\left(\sum_{k=1}^K \Theta_k * f_k(y_t, y_{t-1}, x_t)\right) \end{aligned} \quad (4.4)$$

A joint probability distribution can always be transformed into a conditional probability as shown in eq. (4.5).

$$p(Y|X) = \frac{p(X, Y)}{\sum_{Y' \in S} p(Y', X)} \quad (4.5)$$

The described model so far is a Hidden Markov Model. In a CRF you are also allowed to take only a subset of these features, what can improve performance without loosing accuracy. Additional improvement in a CRF can very likely be achieved by further custom feature functions, which may depend on the whole vector of words, instead of only the current word identity. For example some custom feature functions could be:

- $f_{k+1}(y_t, y_{t-1}, X) = 1_{x_t \text{ startswith upper case}}$
- $f_{k+2}(y_t, y_{t-1}, X) = 1_{x_t \text{ is in a domain specific dictionary}}$
- $f_{k+3}(y_t, y_{t-1}, X) = 1_{x_t \text{ is in a domain specific dictionary and } x_{t-1} \text{ is an article}}$

Putting all together leads to definition 4.1. Note that after plugging eq. (4.4) into eq. (4.5) Z now only depends on X .

Definition 4.1 (linear-chain Conditional Random Field) A linear-chain Conditional Random Field is a conditional distribution of the form:

$$p(Y|X) = \frac{1}{Z(X)} \prod_{t=1}^T \exp(\sum_{k=1}^K \Theta_k * f_k(y_t, y_{t-1}, X)), \text{ where}$$

$$Z(X) = \sum_S \prod_{t=1}^T \exp(\sum_{k=1}^K \Theta_k * f_k(y_t, y_{t-1}, X)) \text{ and}$$

Y vector of labels, X vector of words, S set of all possible labels

Having a CRF in place, a natural prediction function is shown in eq. (4.6). The calculation of $\text{prediction}(X)$ can be done in $(\#S)^2 * \#X$ through dynamic programming.

$$\text{prediction}(X) = \text{argmax}_Y (P(Y|X)) \quad (4.6)$$

4.3.2 Implementation of New York Times

As starting point the New York Times have manually specified labels for over 130,000 ingredient phrases, which they use as training data. They are extracted out of their website, where their recipes are already enriched with Schema.org/Recipe.

One example ingredient phrase is shown in listing 4.2. They use CRF++² as library, which is an implementation of CRF. The first word per column is the actual word. The last word is the label, which should be predicted in IOB2 format. It states, that the beginning of an entity gets prefixed with *B-* and the continuation with *I-*, as you can see in the last three words. Words, which do not belong to a relevant entity, get labelled with *OTHER*. The labels in between are custom features.

and	I7	L12	NoCAP	NoPAREN	I-COMMENT
quartered	I8	L12	NoCAP	NoPAREN	I-COMMENT

Listing 4.2: Extract of the training data for New York Times CRF

The feature functions, which the CRF should use, are not specified through functions in a concrete programming language. Instead they get described through templates of the format `U00:%x[row,column]`, as shown in listing 4.3. The row specifies the targeted word in relative position to itself and the column specifies the absolute position. Therefore when the actual word is mushrooms the data from listing 4.2 would be expended to the values in listing 4.4.

```

Listing 4.4: Derived value when the current word in listing 4.2 is mushrooms

Feature functions are extracted from these templates as shown in listing 4.5. The B-template takes the transition from y_{t-1} to y_t into account. Note that for example the custom feature function, if a word is inside parentheses, gets implemented through adding a label YesPAREN/NoPAREN to the trainings data in the fourth column in a preprocessing step and specifying the feature template U10%[0,4]. Also note, that for each such template $\#(\text{all possible labels}) * \#(\text{all possible words})$ different feature functions gets created. For the B-template $\#(\text{all possible labels}) * \#(\text{all possible labels}) * \#(\text{all possible words})$ different feature functions gets created.

U02:%[0,0]	$\rightarrow 1_{y_t=I-Name \text{ and } x_t=mushrooms}$
U02:%[-2,4]	$\rightarrow 1_{y_t=I-Name \text{ and } x_{t-2} \text{ 4th label is NoPAREN}}$
U13:%x[0,0]/%x[0,2]	$\rightarrow 1_{y_t=I-Name \text{ and } x_t=mushrooms \text{ and } x_t \text{ 2nd label is L12}}$
B	$\rightarrow 1_{y_t=A \text{ and } y_{t-1}=B} \text{ for each } A, B \in \text{possible prediction labels}$

Listing 4.5: Extracting of feature functions from templates

Hence the only features the New York Times take into account for prediction are the word identity (column 0), the index of the current word (column 1), the length of the sentence (column 2, rounded to 4, 8, 12, 16 or 20), if the word starts capitalized (column 3) and if the word is inside parenthesis (column 4).

When applying their algorithm to 481 example recipes, they get 89% sentence-

level accuracy, meaning that they get 9 out of 10 ingredient phrases completely right. They tested only so few recipes, although they had over 130,000 ready labelled recipes, because they found no way for automatic evaluation. Their problem was, that there were too many ambiguous phrases and too many mistakes in the manually labelled data.

4.4 Domain Specific Information Extraction for Semantic Annotation

(Ahmed 2009) is a diploma thesis about extracting ingredients and their further processing from recipes. Their algorithm could be divided into two main parts.

First to check every word, if it is in a dictionary of ingredients respectively a dictionary of actions and label it accordingly. For keeping the dictionaries as small as possible they do a morphological Analysis and only store the lemmas of the words. The second main part, and more sophisticated task, is to identify, which action should be applied to which ingredient. They have a rule based approach and a dependency parsing based approach for that.

The rule based approach is to do a part of speech tagging (POS) first and afterwards try to apply a small set of rules, which define a context free grammar, with predefined meaning. Listing 4.6 shows an example, meaning buttermilk and bananas should be added.

```
# Example sentence
add buttermilk and bananas

# Example sentence with POS and dictionary-label
add[ACT] buttermilk[ING] and[CC] bananas[ING]

# Apply rule VP -> ACT NP (,NP)* (CC NP)?
# Predefined meaning of the rule: Apply ACT to all ING
-> ACT NP CC NP
# Apply rule NP -> DT? JJ* ING twice
-> ACT ING CC ING

# With:
# VP, NP ∈ non-terminal symbols, CC ∈ Conjunctions, DT ∈ Determiner,
  ACT := action, ING := ingredient
```

Listing 4.6: Rule based example

The second approach is to do a dependency based parsing, which represents the semantic structure of a sentence in a tree like format. For example fig. 4.1 represents, that the subject of like is John and the liked object is Apple. The format as well as building the tree is way more complex than the previous simple rules, but the tree can be build by already existing tools like the Stanford Parser³. The semantic structure of the sentences give strong evidence, which action should be applied to which ingredient.

³<http://nlp.stanford.edu/software/lex-parser.shtml>

Figure 4.1: John likes apple (Ahmed 2009)

In their evaluation they apply these two variants to 43 randomly selected recipes from the internet. Their precision and recall are presented in table 4.1. Even the more sophisticated dependency based approach has only a recall of 64%. This is due to a lack of mapping actions to their corresponding ingredients.

	Precision	Recall
Rule based	97.39%	51.54%
Dependency Based	95.4%	64.12%

Table 4.1: Evaluation Domain Specific Information Extraction for Semantic Annotation

4.5 Data-driven Knowledge Extraction for the Food Domain

(Wiegand et al. 2012)

4.6 Distinction to this work

(*Skip The Pizza* 2012) exploits a strict semi-structure, which is not given in our very unstructured cookbook. Therefore we need more advanced algorithm than regular expressions.

(The New York Times 2015) take advantage of the point, that they have already marked the ingredient phrases from the list of ingredients. But our cookbook has no list of ingredients. Nevertheless, the ingredient phrases could be extracted from plain text through a CRF algorithm first and afterwards we could use the algorithm of (The New York Times 2015). However we have to consider, that we do not have near as 130,000 training data. Our lack of training data could be caught up by more sophisticated custom feature functions. Maybe good feature functions even enable to extract all wanted data in one CRF algorithm.

(Ahmed 2009) only uses plain text.(Lüge??) But they have a bad recall, due to the point, that they are not good in mapping actions to their corresponding ingredients. In contrast to mapping actions to ingredients, we want to map quantities to units and these in turn to ingredients, which is more complex and could therefore lead to an even worse recall. Though the dictionary check, enabled by a morphological analysis, from their algorithm first main part, could be very good feature functions.

Chapter 8

Discussion

8.1 Übertragung auf beliebige / allgemeine Rezepte

8.2 Rapid Prototyping

- TDD / früh Plausibilitäts-Überprüfungen - Tagen als Hi-Wi war ne dumme Aktion (insbesondere fürs Schemata, Mengenangaben und Namen historische Recherche nötig (B-17 bzw appendix B cook time not clear / Gefühl für die Daten, Wurzelwerk, braunes Gewürz, Engl. Soja)) - CRF zu aufwändig

8.3 Güte der Daten

- Mengenangaben ohne recipeYield witzlos - links/refs erschweren Auswertung - BLS Angaben für alk. freie Getränke :D :D :D - welche Zutat welche BLS key - Übersetzung von Mengenangaben (Maß)

8.4 Knowledge is power

https://en.wikipedia.org/wiki/Scientia_potentia_est

Machine readable data are very powerful. But *with great power comes great responsibility*¹². In the context of a recipe parser this might be a little bit exaggerated. But specially in mind of the global surveillance disclosures denounced by Edward Snowden with still uncertain dimension, I think it is important to have a consciousness for what can be done. Therefore I want to think about, what can be done through innocent looking machine readable tags.

In the bad (The Washington Post 2016) - I seriously wonder if revealing Hillary were a vegetarian would have a bad impact on her survey results.

¹A well known proverb which probably has its origin from the French National Convention during the period of French Revolution. (*With Great Power Comes Great Responsibility* 2015)

²In "Die Physiker" sehr gut thematisiert

Appendix B

Full example use of cueML

```
<recipe type="Suppen." rcp-id="B-16">
  <head>Mock Turtle Suppe.</head>

  <p>Es wird hierzu für 24-30 Personen eine kräftige Bouillon von
    8-10 Pfund Rindfleisch mit Wurzelwerk gekocht. Zugleich bringt
    man einen großen Kalbskopf, eine Schweineschnauze und Ohren,
    einen OchsenGaumen und eine geräucherte Ochsenzunge zu Feuer
    und kocht dies Alles gahr, aber nicht zu weich. Kalt,
    schneidet man es in kleine, länglich viereckige Stückchen,
    gibt das Fleisch in die Bouillon, nebst braunem Gewürz, ein
    Paar Messerspitzen Cayenne-Pfeffer, einige Kalbsmidder in Stü
    ckchen geschnitten (siehe Vorbereitungsregeln), kleine
    Saucissen, so viel Kalbskopfb Brühe, daß man hinreichend Suppe
    hat, und macht dies mit in Butter braun gemachtem Mehl
    gebunden. Nachdem dies Alles 1/4 Stunde gekocht hat, kommen
    noch Klöße von Kalbfleisch, einige hart gekochte Eier in Wü
    rfel geschnitten, ein Paar Eßlöffel Engl. Soja hinzu, und wenn
    die Klößchen einige Minuten gekocht haben, 1/2 Flasche
    Madeira und auch Austern, wenn man sie haben kann. Dann wird
    die Suppe sogleich angerichtet.</p>

  <note>Anmerk. Der Soja macht die Suppe gewürzreicher, kann jedoch
    gut wegbleiben, und statt Madeira kann man weißen Franzwein
    und etwas Rum nehmen. Sowohl die Bouillon als Kalbskopf können
    schon am vorhergehenden Tage, ohne Nachtheil der Suppe,
    gekocht werden. </note>
